## Bayes' Theorem: Updating with New Data

## Video companion

## 1 Updating probabilities

Bayes' theorem allows for updating probabilities based on new data.

From previous solution:

| Process |                  | P(white marble) |
|---------|------------------|-----------------|
| Urn 1   | $\overline{A_1}$ | 20%             |
| Urn 2   | $A_2$            | 10%             |

 $P(\text{Urn 1} \mid 3 \text{ white marbles in a row}) = 8/9$  $P(\text{Urn 2} \mid 3 \text{ white marbles in a row}) = 1/9$ 

**New information:** We draw a fourth marble that is also white.

 $P(A_1)$  and  $P(A_2)$  become our new prior probabilities or new priors.

 $P(\text{urn } 1 \mid 3 \text{ white marbles in a row, } and \text{ a 4th})$ 

$$= \frac{P(\text{white} \mid \text{urn 1})P(\text{urn 1})}{P(\text{white} \mid \text{urn 1})P(\text{urn 1}) + P(\text{white} \mid \text{urn 2})P(\text{urn 2})}$$
$$= \frac{(0.2)(8/9)}{(0.2)(8/9) + (0.1)(1/9)}$$

$$P(\text{urn 1}) = 94.12\%$$

$$P(\text{urn 2}) = 5.88\%$$

## 2 Technical vocabulary

Technical vocabulary of Bayesian inverse probability:

$$\underbrace{P(\theta_i \mid D)}_{\text{posterior probability}} = \underbrace{\frac{P(D \mid \theta_i)}{P(\theta_i)}}_{\text{marginal probability}} \underbrace{\frac{P(D \mid \theta_i)}{P(\theta_i)}}_{\text{marginal probability}}$$

posterior probability—probability after new data is observed prior probability—probability before any data is observed or before new data is observed likelihood—standard forward probability of data given parameters marginal probability—probability of the data
